

JULY 2 and 3, 1948 The patients came from the MILITARY BASE, from the FIRST COMPANY OF FUSILIERS. They were all observed for one week before the experiment by testing 3 cultures of their first morning urine sample. All of the patients had been in contact with women who had not been infected with gonorrhea. The data concerning the contacts can be seen in the table below. After the contact the patients were inoculated at the times indicated below. The pus was extracted from the donor using a tuberculin syringe moistened with PP#3.

For both nights the pus used for the inoculation came from 4 donors:

#1 [REDACTED] #12. [REDACTED] #33 [REDACTED] and #39. [REDACTED] patients from the June 28-29 experiment. The pus was collected at 7:10 and 7:20 PM.

For the inoculation, swabs moistened with PP#3 were used; the same swab was used for all of them each night. Using a #24 needle, a drop of pus was applied to the swab and was then gently placed in the navicular fossa of the penis, making sure to not enter deeply into the urethra. This is the same method as the one used for all the previously performed inoculations.

The controls were inoculated with a swab made out of a toothpick and cotton. Using a #24 needle, a drop of pus was applied to the swab. The swab was then inserted ½ an inch into the urethra and was carefully applied to the mucous membrane of the urethra.

All patients abstained from urinating until immediately before applying the prophylaxis, when a sample of urine was taken to test for sulfa. After urinating, the patients, excluding the controls, received prophylaxis applied by the physicians.

PENICILLIN: Each patient received 300,000u of Oral Penicillin CSC Lot No.

ARGYROL: A 10% solution was prepared immediately before use. All patients treated with Argyrol were washed with the solution for 2 minutes paying special attention to put a bit of the solution into the navicular fossa. The method was the same used for the usual application of the RCA prophylaxis.
